

Converting GPS Coordinates to Decimal Degrees in Excel

LOCATION DATA

Geographic Information System (GIS) data, including latitude and longitude, are commonly created with Global Positioning System (GPS) technology. Latitude (angular distance from the equator) and longitude (angular distance from the Prime Meridian) are recorded as part of location-based data collection. A GPS has the ability to collect latitude and longitude in several different formats. **The Dev aWhere platform requires latitude and longitude to be submitted in a standard format called decimal degrees.** Decimal degrees expresses latitude and longitude as decimal fractions, and is an alternative to using degrees, minutes, seconds or UTM.

CONVERTING FROM DEGREES, MINUTES, SECONDS TO DECIMAL DEGREES

Latitudes and longitudes stored as degrees, minutes, and seconds can easily be converted to decimal degrees in Excel using the formula:

$$\text{Decimal degrees} = \text{degrees} + (\text{minutes}/60) + (\text{seconds}/3600)$$

GPS coordinates stored as degrees, minutes, seconds must have a direction associated with them (i.e., North/South, East/West). If latitude is south, then latitude in decimal degrees will be negative (-). If longitude is west, then in longitude in decimal degrees will be negative (-).

USING TEXT TO COLUMNS

The first step is to ensure that you have latitude and longitude stored in two separate columns.

14	CUES017	Cachite	10/23/2013	S 15 01. 925; E 034 12. 943		E 034 12. 943
15	GACR018	Nhazira	10/23/2013	S 16 00. 397; E 034 12. 238		E 034 12. 238

Latitude and longitude can easily be separated into two columns using the **Text to Columns** tool, found on the **Data** tab.

First highlight the column containing the data to be separated, and then click **Text to Columns**.

The screenshot shows the Excel interface with the 'Data' tab selected. The 'GPS Coordinates' column (D) is highlighted. The 'Text to Columns' wizard is open, showing Step 1 of 3. The wizard has determined that the data is 'Fixed Width'. The preview shows the following data:

1	GPS Coordinates
2	S 15 34. 190; E 034 26. 286
3	S 15 08. 831; E 034 17. 117
4	S 15 32. 315; E 034 26. 436
5	S 15 34. 250; E 034 25. 990

Then decide whether the data values are delimited or fixed width. In this example, you could choose either because the values, latitude and longitude, are consistently spaced within the cell (i.e. fixed width), and they are separated (i.e. delimited) by a semicolon (;). With 'delimited', the semi-colon will be removed automatically. With 'fixed width', the semicolon must be removed from the cells. **Note:** The semicolon can easily be replaced with the **'Find and Replace'** tool.

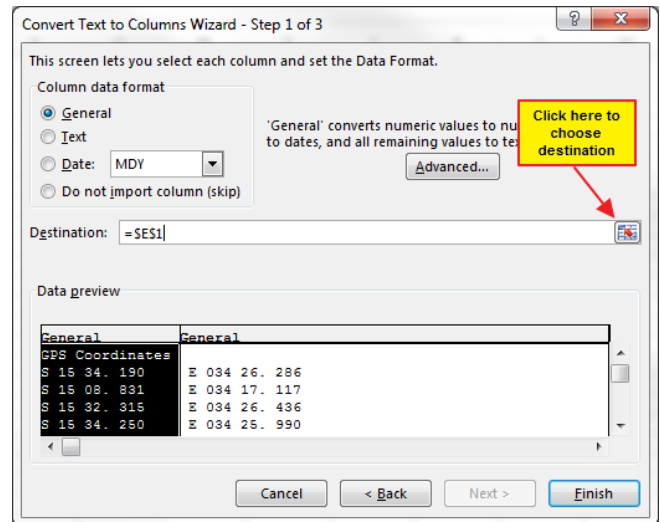

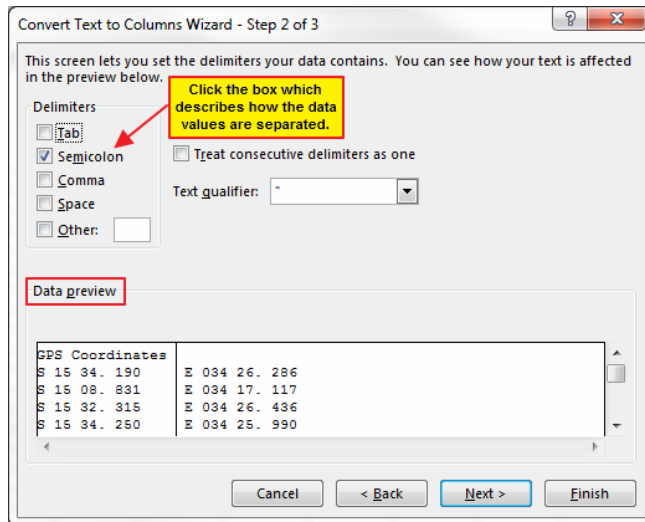

DELIMITED

In this case, latitude and longitude are separated by a semi-colon. They can be separated into two columns using the **'Delimited'** option.

First determine which character separates your data. You will notice that when you select "Semicolon", a line appears in the Data Preview, separating the value for latitude, from the value for longitude. If it looks correct, click 'Next'.

On the next screen, select a destination for the new columns of data. The destination should be the first cell of a blank column. Once you've selected the destination click "Finish".

*To insert a new column, highlight a column, right click and select 'Insert'.

FIXED WIDTH

Once you have latitude and longitude in separate columns, you can separate them further by element - degrees, and in this case, decimal minutes. **Note:** In this case, there is no 'seconds' value – only degrees and decimal minutes.

If the contents of the cell are evenly spaced in the cell, you can separate them into two columns using the 'Fixed width' option. First highlight the column containing latitude and then click '**Text to Columns**' and this time select '**Fixed width**'.

Since latitude is formatted as degrees, decimal minutes, remove the line separating the decimal minutes. The output should be three columns – one for the sign (i.e. direction - N/S), one for degrees, and one for decimal minutes.

16	GACR018	Nhazira	10/23/2013	S 16 00. 397; E 034 12. 238	S 16 00. 397		S	16	00. 397

Now we can write a formula to calculate decimal degrees.

CALCULATING DECIMAL DEGREES

The formula for converting degrees, minutes, seconds to decimal degrees is:

$$\text{Decimal degrees} = \text{degrees} + (\text{minutes}/60) + (\text{seconds}/3600)$$

Since degrees and decimal minutes are separated into separate columns, we can easily write a formula in Excel to calculate decimal degrees. It's important to add a negative sign to the beginning of the formula because latitude is South. If the sign/direction is North, then latitude would remain positive.

SUM						
	E	F	G	H	I	J
	Latitude		Sign	Degrees	Decimal Minutes	
1						
2	S 15 34. 190		S	15	34.190	=(-(H2+(I2/60)))
3	S 15 08. 831		S	15	8.831	
4	S 15 32. 315		S	15	32.315	
5	S 15 34. 250		S	15	34.250	
6	S 15 32. 261		S	15	32.261	

Tip: Insert a new column for the formula, and then use auto fill to fill in the rest of the rows. To do so, hover over the lower right-hand corner of the cell containing the formula until a plus sign appears.

J9						
	E	F	G	H	I	J
	Latitude		Sign	Degrees	Decimal Minutes	
1						
2	S 15 34. 190		S	15	34.190	-15.569833
3	S 15 08. 831		S	15	8.831	
4	S 15 32. 315		S	15	32.315	
5	S 15 34. 250		S	15	34.250	
6	S 15 32. 261		S	15	32.261	
7	S 15 32. 400		S	15	32.400	
8	S 15 33. 558		S	15	33.558	

Repeat the process for longitude.
